# Recursion

Computing Laboratory

`http://www.isical.ac.in/~dfslab`

# Recursion

**A recursive function is a function that calls itself.**

- The task should be decomposable into sub-tasks that are smaller, but otherwise identical in structure to the original problem.
- The simplest sub-tasks (called the base case) should be (easily) solvable directly, i.e., without decomposing it into similar sub-problems.

# Recursive vs. iterative implementations

```c
int factorial ( int n ) {
   int prod;

   if (n < 0) return (-1);
   prod = 1;
   while (n > 0) {
      prod *= n;
      n = n - 1;
   }
   return (prod);
}
```

# Recursive vs. iterative implementations

```c
int factorial ( int n )           /* Recursive implementation */
{
   if (n < 0) return (-1);        /* Error condition */
   if (n == 0) return (1);        /* Base case */
   return(n * factorial(n-1));    /* Recursive call */
}
```
# Z curve

## Problem statement

Consider a 2-D matrix of size $2^m \times 2^m$. The entries of the matrix are, in row-major order, $1, 2, 3, \ldots, 2^{2m}$. Print the entries of the matrix in Z-curve order (as shown in the picture below).

# Z curve: structure

$(0, 0)$

$(N - 1, N - 1)$
**Problem structure:**
- *Base case:* single element
- Recursive structure:
  - break given square into 4 sub-squares
  - process squares in Z-curve order

# Z curve: code I

```c
void z_curve(int top_left_row, int top_left_column,
             int bottom_right_row, int bottom_right_column,
             int **matrix)
{
    /* Base case */
    if (top_left_row == bottom_right_row &&
        top_left_column == bottom_right_column) {
        printf("%d ", matrix[top_left_row][top_left_column]);
        return;
    }

    /* Recurse */

    /* upper-left sub-square */
    z_curve(top_left_row,
            top_left_column,
            (top_left_row + bottom_right_row)/2,
```

```
        (top_left_column + bottom_right_column)/2,
        matrix);

/* upper-right sub-square */
z_curve(top_left_row,
        (top_left_column + bottom_right_column)/2 + 1
        (top_left_row + bottom_right_row)/2,
        bottom_right_column,
        matrix);

/* lower-left sub-square */
z_curve((top_left_row + bottom_right_row)/2 + 1,
        top_left_column,
        bottom_right_row,
        (top_left_column + bottom_right_column)/2,
        matrix);

/* lower-right sub-square */
```

```
    z_curve((top_left_row + bottom_right_row)/2 + 1,
            (top_left_column + bottom_right_column)/2 + 1,
            bottom_right_row, bottom_right_column,
            matrix);
    return;
}
```

# Permutations

### Algorithm

To generate all permutations of $1, 2, 3, \ldots, n$, do the following:
1. Generate all permutations of $2, 3, \ldots, n$, and add $1$ to the beginning.
2. Generate all permutations of $1, 3, 4, \ldots, n$ and add $2$ to the beginning.

   . . .
n. Generate all permutations of $1, 2, \ldots, n-1$ and add $n$ to the beginning.

# Permutations: code

```c
void permute(int *A, int k, int n)
{
    int i;

    if(k==n) {
        for (i = 0; i < n; i++) {
            printf("%d ", A[i]);
        }
        putchar('\n');
        return;
    }

    for(i = k; i < n; i++){
        SWAP(A, i, k);
        permute(A, k+1, n);
        SWAP(A, k, i);
    }

    return;
}
```
# Problems – I

1. Towers of Hanoi: see
   https://en.wikipedia.org/wiki/Tower_of_Hanoi

   

   CC BY-SA 3.0, https://commons.wikimedia.org/w/index.php?curid=228623

2. Write a recursive function with prototype `int C(int n, int r);` to
   compute the binomial coefficient using the following definition:

   $$\binom{n}{r} = \binom{n-1}{r} + \binom{n-1}{r-1}$$

   Supply appropriate boundary conditions.

3. Define a function $G(n)$ as:

$$G(n) = \begin{cases} 0 & \text{if } n = 0 \\ 1 & \text{if } n = 1 \\ 2 & \text{if } n = 2 \\ G(n-1) + G(n-2) + G(n-3) & \text{if } n \geq 3 \end{cases}$$

Write recursive **and** iterative (i.e., non-recursive) functions to compute $G(n)$.

4. What does the following function compute?
```
int f ( int n )
{
    int s = 0;
    while (n--) s += 1 + f(n);
    return s;
}
```

# Problems – IV

6. In chess, a knight can move to a cell that is horizontally 2 cells and vertically 1 cell away, or vertically 2 cells and horizontally 1 cell away (see Fig. 6). Thus, eight moves are possible for a knight in general.
Given an $m \times n$ chess-like board, and a knight at position $(i, j)$ (where $0 \leq i < m$ and $0 \leq j < n$), compute the probability that the knight remains on the board after a given number (say $k$) of steps, assuming that, at each step, all eight moves are equally likely. Note that, once the knight moves off the board, it can never return to the board.

**Input Format**

$m\ n\ i\ j\ k$

**Output Format**

The probability value rounded up to 6 decimal places.

**Sample Input 0**

1 2 0 1 1

**Sample Output 0**

0.000000

**Sample Input 1**

8 8 3 3 1

**Sample Output 1**

1.000000

**Sample Input 2**

6 6 0 0 1

**Sample Output 2**

0.250000

**Sample Input 3**

4 4 0 0 2
**Sample Output 3**
0.125000
**Explanation for the above**

|   | 0 | 1 | 2 | 3 |
|---|---|---|---|---|
| 0 | 0/2/2 |   | 2 |   |
| 1 |   |   | 1 | 2 |
| 2 | 2 | 1 |   |   |
| 3 |   | 2 |   | 2/2 |

The knight starts at the top-left corner (0,0). After 1 move, it may either move off the board (permanently), or go to the squares marked 1 (in red / blue). After another move from the square marked with a red (respectively, blue) 1, it lands on one of the squares marked with a red (respectively, blue) 2, or moves off the board. The knight stays on the board for 8 distinct sequences of moves (of 2 steps each). The total number of such moves of 2 steps each is $8 \times 8 = 64$.

7. Write a program that takes a positive integer $n \leq 5$, and a non-negative integer $k \leq 100$ as command-line arguments, and computes the total number of cells reachable from any starting cell within an infinite, $n$-dimensional grid in $k$ steps or less. See the examples below. You are only permitted to travel in a direction that is parallel to one of the grid lines; diagonal movement is not permitted.
**NOTE:** If you are interested, you may compute a closed-form expression for the required number, but **DO NOT** use the closed-form expression to compute the answer to this problem.

Starting Cell

$n = 1, k = 2$; number of cells reachable = 5

$n = 2, k = 2$; number of cells reachable = 13
For $n = 3$, your output for $k = 0, 1$ and $2$ should be 1, 7, and 25, respectively.
